PHOTON COUNTING
Using Photomultiplier Tubes

HAMAMATSU

INTRODUCTION

Recently, non-destructive and non-invasive measurement using light is becoming more and more popular in diverse fields including biological, chemical, medical, material analysis, industrial instruments and home appliances. Technologies for detecting low level light are receiving particular attention since they are effective in allowing high precision and high sensitivity measurements without changing the properties of the objects.

Biological and biochemical examinations, for example, use low-light-level measurement by detecting fluorescence emitted from cells labeled with a fluorescent dye. In clinical testing and medical diagnosis, techniques such as in-vitro assay and immunoassay have become essential for blood analysis, blood cell counting, hormone inspection and diagnosis of cancer and various infectious diseases. These techniques also involve low-light-level measurement such as colorimetry, absorption spectroscopy, fluorescence photometry, and detection of light scattering or luminescence measurement. In RIA (radioimmunoassay) which has been used in immunological examinations using radioisotopes, radiation emitted from a sample is converted into low level light which must be measured with high sensitivity. In biological application, precise detection of the receptor gene expression is becoming important. The reporter genes are labeled with fluorescence or chemiluminescence substances to give off light at expression.

Photomultiplier tubes, photodiodes and CCD image sensors are widely used as "eyes" for detecting low level light. These detectors convert light into analog electrical signals (current or voltage) in most applications. However, when the light level becomes weak so that the incident photons are detected as separate pulses, the single photon counting method using a photomultiplier tube is very effective if the average time intervals between signal pulses are sufficiently wider than the time resolution of the photomultiplier tube. This photon counting method is superior to analog signal measurement in terms of stability, detection efficiency and signal-to-noise ratio.

This technical manual explains how to use photomultiplier tubes in photon counting to perform low-light-level measurement with high sensitivity and high accuracy. This manual also describes the principle of photon counting, its key points and operating circuit configuration, as well as characteristics of photomultiplier tubes and their selection guide.

TABLE OF CONTENTS
1. What is Photon Counting ?

1-1 Analog Mode and Digital Mode (Photon Counting Mode)

A photomultiplier tube (PMT) consists of a photocathode, an electron multiplier (composed of several dynodes) and an anode. (See Figure 2 for schematic construction.) When light enters the photocathode of a photomultiplier tube, photoelectrons are emitted from the photocathode. These photoelectrons are multiplied by secondary electron emission through the dynodes and then collected by the anode as an output pulse. In usual applications, these output pulses are not handled as individual pulses but dealt with as an analog current created by a multitude of pulses (so-called analog mode). In this case, a number of photons are incident on the photomultiplier tube per unit time as in ① of Figure 1 and the resulting photoelectrons are emitted from the photocathode as in ②. The photoelectrons multiplied by the dynodes are then derived from the anode as output pulses as in ③. At this point, when the pulse-to-pulse interval is narrower than each pulse width or the signal processing circuit is not fast enough, the actual output pulses overlap each other and eventually can be regarded as electric current with shot noise fluctuations as shown in ④.

In contrast, when the light intensity becomes so low that the incident photons are separated as shown in ⑤, the output pulses obtained from the anode are also discrete as shown in ⑦. This condition is called a single photoelectron state. The number of output pulses is in direct proportion to the amount of incident light and this pulse counting method has advantages in signal-to-noise ratio and stability over the analog mode in which an average of all the pulses is made.

This pulse counting technique is known as the photon counting method. Since the detected pulses undergo binary processing for digital counting, the photon counting method is also referred to as the digital mode.

Figure 1 : Output Pulses from Photomultiplier Tube at Different Light Levels

1-2 The Principle of Photon Counting

One important factor in photon counting is the quantum efficiency (QE). It is the production probability of photoelectrons being emitted when one photon strikes the photocathode. In the single photoelectron state, the number of emitted photoelectrons (primary electrons) per photon is only 1 or 0. Therefore QE refers to the ratio of the average number of emitted electrons from the photocathode per unit time to the average number of photons incident on the photocathode.

Figure 2 : Photomultiplier Tube Operation in Single Photoelectron State

TPMOC0048EB
Photoelectrons emitted from the photocathode are accelerated and focused onto the first dynode (Dy1) to produce secondary electrons. However, some of these electrons do not strike the Dy1 or deviate from their normal trajectories, so they are not multiplied properly. This efficiency of collecting photoelectrons is referred to as the collection efficiency (CE). In addition, the ratio of the count value (the number of output pulses) to the number of incident photons is called the detection efficiency or counting efficiency, and is expressed by the following equation :

$$\text{Detection efficiency} = N\text{d} / N\text{p}$$
$$= \eta \times \alpha$$

where Nd is the count value, Np is the number of incident photons, η is the photocathode QE and α is the CE. Although it will be discussed later, detection efficiency also depends on the threshold level that brings the output pulses into a binary signal. Since the number of secondary electrons emitted from the Dy1 varies from several to about 20 in response to one primary electron from the photocathode, they can be treated by Poisson distribution in general, and the average number of secondary electrons becomes the secondary electoron emission ratio δ. This holds true for multiplication processes in the subsequent dynodes. Accordingly, for a photomultiplier tube having n stages of dynodes, a single photoelectron from the photocathode is multiplied by δ^n to create a group of electrons and is derived from the anode as an output pulse. In this process, the height of each output pulse obtained at the anode depends on fluctuations in the secondary electron multiplication ratio stated above, so that it differs from pulse to pulse. (Figure 3)

Other reasons why the output pulse height becomes unequal are that gain varies with the position on each dynode and some deviated electrons do not contribute to the normal multiplication process. Figure 3 shows a histogram of the anode pulse heights. This graph is known as the pulse height distribution (PHD).

As illustrated in Figure 3, the photomultiplier tube output exhibits fluctuations in the pulse height and the PHD is obtained by time-integrating these output pulses at different pulse heights. The abscissa of this graph indicates the pulse height that represents the charge (number of electrons contained in one electron group) or the pulse voltage (current) produced by that electron group. It is generally expressed in the number of channels used for the abscissa of a multichannel analyzer.

Figure 3 : Photomultiplier Tube Output and PHD

TPMOC0049EB
Photomultiplier Tube Output in Single Photoelectron State

The output signal from a photomultiplier tube in the photon counting mode can be calculated as follows:

In the photon counting mode, a single photoelectron e^- (electron charge:1.6×10^{-19} C) is emitted from the photocathode. If the photomultiplier tube gain μ is 5×10^6, then the anode output charge is given by

$$e \times \mu = 1.6 \times 10^{-19} \times 5 \times 10^6 \text{ C}$$
$$= 8 \times 10^{-13} \text{ C}$$

Here, if the pulse width t (FWHM) of the anode output signal is 10 ns, then the output pulse peak current Ip is

$$I\text{p} = e \times \mu \times 1/t \text{ A}$$
$$= (8 \times 10^{-13}) \text{ C} / (10 \times 10^{-9}) \text{ s}$$
$$= 80 \mu \text{A}$$

This means that the anode output pulse width is narrower, we can obtain much higher output peak current. If the load resistance or input impedance of the succeeding amplifier is 50 Ω, the output pulse peak voltage Vo becomes

$$V\text{o} = I\text{p} \times 50 \text{ }\Omega$$
$$= 4 \text{ mV}$$

The amplitude of the photomultiplier tube output pulse in the photon counting mode is extremely small. This requires a photomultiplier tube having a high gain and may require an amplifier with sufficiently low noise relative to the photomultiplier tube output noise. As a general guide, photomultiplier tubes should have a gain of approximately 1×10^6 or more.

Figure 4 (a) shows a PHD when the incident light level is increased under single photoelectron conditions, and (b) shows a PHD when the supply voltage is changed.

The ordinate is the frequency of the output pulses that produce a certain height within a given time. Therefore, the distribution varies with the measurement time or the number of incident photons in the upper direction of the ordinate as shown in Figure 4 (a).
As explained above, the abscissa of the PHD represents the pulse height and is proportional to the gain of the photomultiplier tube and becomes a function of the supply voltage of the photomultiplier tube. This means that as the supply voltage changes, the PHD also shifts along the ordinate, but the total number of counts is almost constant.

2. Operation and Characteristics of Photon Counting

This section describes circuit configurations for use in photon counting and the basic characteristics of photon counting measurements.

2-1 Photon Counter and Multichannel Pulse Height Analyzer

There are two methods of signal processing in photon counting: one uses a photon counter and the other a multichannel pulse height analyzer (MCA). Figure 5 shows the circuit configuration of each method and the pulse shapes obtained from each circuit system.

In the photon counter system of Figure 5 (a), the output pulses from the photomultiplier tube are amplified by the preamplifier. These amplified pulses are then directed into the discriminator. The discriminator compares the input pulses with the preset reference voltage to divide them into two groups: one group is lower and the other is higher than the reference voltage. The lower pulses are eliminated by the lower level discriminator (LLD) and in some cases, the higher pulses are eliminated by the upper level discriminator (ULD). The output of the comparator takes place at a constant level (usually a TTL level from 0 V to 5 V, or an ECL level of −0.9 V to −1.7 V for high-speed output). The pulse shaper forms rectangular pulses allowing counters to count the discriminated pulses.

In contrast, in the MCA system shown in Figure 5 (b), the output pulses from the photomultiplier tube are generally integrated through a charge-sensitive amplifier, amplified and shaped with the linear amplifier. These pulses are discriminated according to their heights by the discriminator and are then converted from analog to digital. They are finally accumulated in the memory and displayed on the screen. This system is able to output pulse height information and frequency (the number of counts) simultaneously, as shown in the figure.

The photon counter system is used to measure the number of output pulses from the photomultiplier tube corresponding to incident photons, while the MCA system is used to measure the height of each output pulse and the number of output pulses simultaneously. The former system is superior in counting speed and therefore used for general-purpose applications. The MCA system has the disadvantage in not being able to measure high counts, it is used for applications where pulse height analysis is required.
Figure 5 : Typical Photon Counting Systems

2-2 Basic Characteristics in Photon Counting

(1) Pulse Height Distribution and Plateau Characteristics

Figure 6 shows pulse height distributions (PHD) of a photomultiplier tube, obtained with an MCA. The curve (a) is the output when signal light is incident on the photomultiplier tube, while the curve (b) represents the noise when signal light is removed. The major noise component results from thermionic emission from the photocathode and dynodes. The PHD of such noise usually appears on the lower pulse height side. These PHD are the so-called differential curves and the lower level discrimination (LLD) is usually set at the valley of the curve (a). To increase detection efficiency, it is advantageous to set the LLD at a lower position, but this is also accompanied by a noise increase.

In contrast to the curve (a) in Figure 6, the curve (c) shows an integration curve in which the total number of pulses higher than a certain discrimination level have been plotted while changing the discrimination level. Since this integration curve (c) has an interrelation with the differential curve (a), the proper discrimination levels can be set in the photon counter system without using an MCA, by obtaining the integration curve instead.

The LLD stated above corresponds to a pulse height on a gentle slope portion in the integration curve. But this is not so distinct from other portions, making it difficult to determine the LLD. Another method using plateau characteristics is more commonly used. By counting the number of pulses with the LLD fixed while varying the supply voltage to the photomultiplier tube, a curve similar to the "SIGNAL+NOISE" curve shown in Figure 7 can be plotted. Although, analog gain increases expotentially with supply voltage, since the photomultiplier tube counts only the number of pulses, the slope of the curves is relatively flat, which makes the supply voltage setting easier. These curves are known as the plateau characteristics. The supply voltage for the photomultiplier tube should be set within this plateau region. It is also clear that plotting the signal-to-noise ratio shows a plateau range in the same supply voltage range. (See Section 3-8 (2).)

Figure 7 : Plateau Characteristics

Figure 6 : Differential and Integral Displays of PHD

6
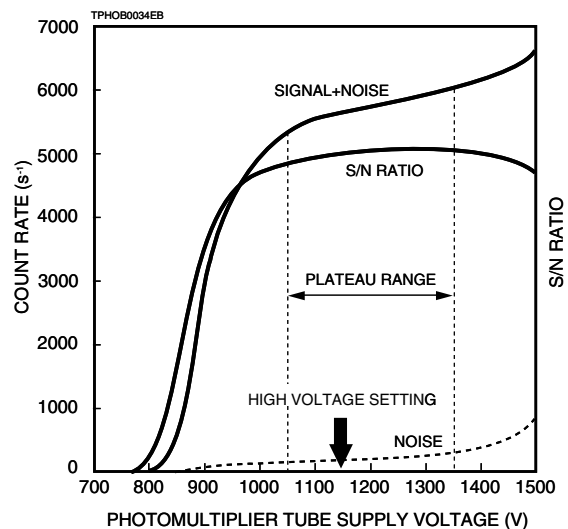

(2) Output Instability vs. Variations in Photomultiplier Tube Gain

If the photomultiplier tube gain varies for some reason (for example, a change in supply voltage or fluctuations in the ambient temperature, etc.), the output current of the photomultiplier tube is also affected and exhibits variations. In the analog mode the output current (or gain) of the photomultiplier tube changes with variations in the supply voltage as shown in Figure 8 (a). In the photon counting mode, the output count changes, but this is significantly smaller than in the analog mode.

By setting the supply voltage in the plateau region as shown in Figure 7, the photon counting mode can minimize changes in the count rate with respect to variations in the supply voltage, without sacrificing the signal-to-noise ratio. This means that the photon counting mode ensures high stability even when the gain of the photomultiplier tube varies, as the gain is a function of the supply voltage. For the above reasons, the photon counting mode offers several times higher stability than the analog mode versus variations in the operating condtions.

Figuer 8 : Output Variation vs. Supply Voltage
How to Obtain the Plateau

Speaking it in a broad sence, the integration curve explained in Section 2-2 (1) has plateau characteristics. Here we describe a more practical method for obtaining the plateau characteristics by varying the photomultiplier tube supply voltage.

1. Set up the photomultiplier tube, photon counter, high-voltage power supply, dark box, light source, etc, required to perform photon counting. Preferably, the photomultiplier tube should be stored in the dark box for about one hour after the setup has been completed.
2. Set the discrimination level (LLD) according to the instruction manual for the photon counter being used. Then allow a very small amount of light to strike the photomultiplier tube.
3. Gradually increase the photomultiplier tube supply voltage starting from about 500 V. When the photon counter begins to count any signal, halt there and make a plot of the supply voltage (V_L) and the counted value at that point, on a graph with the abscissa showing the supply voltage and the ordinate representing the count rate.
4. Increase the supply voltage with a 50 V step until it reaches about 90 % (V_H) of the maximum supply voltage while making plots on the graph. This will create a curve like "A" shown in Figure 9.

5. With the photomultiplier tube operated at a voltage (V_C) in the middle of the flat portion of curve "A", adjust the light source intensity so that the counted value is set to 10 % to 30 % of the maximum count rate of the photon counter.
6. Readjust the photomultiplier tube supply voltage to set at V_L, then make fine plots while changing the photomultiplier tube supply voltage in 10 V or 20 V steps. This will make a curve like "B" shown in Figure 9.
7. In the flat range (plateau range) on curve "B", the voltage V_C' at a point where the differential coefficient is smallest (minimum slope) will be the optimum PMT operating voltage.

Figure 9 : Plotting Plateau characteristics

7
(3) Linearity of Count Rate

The photon counting mode is generally used in very low-light-level regions where the count rate is low, and exhibits good linearity. However, when the amount of incident light becomes large, it is necessary to take the linearity of the count rate into account. The upper limit of the bandwidth of photomultiplier tubes ranges from 30 MHz to 300 MHz for periodical signal. Therefore, the maximum count rate in the photon counting mode where random photos enter the photomultiplier tube is determined by the type of photomultiplier tube and the time resolution of the signal processing circuit connected to the photomultiplier tube. The time resolution referred to here is defined as the minimum time interval between successive pulses that can be counted as separate pulses.

Figure 10 shows a typical linearity of the count rate obtained from a Hamamatsu H6180-01 Photon Counting Head. As can be seen from the figure, the dynamic range reaches as high as 10^7 s^{-1}. In this case, the linearity of the count rate is limited by the time resolution (pulse pair resolution) of the built-in circuit (18 ns).

If we let the measured count rate be N' (s^{-1}) and the time resolution be t (s), the real count rate N (s^{-1}) can be approximated as follows:

$$N = \frac{N'}{1 - N't}$$

Figure 11 shows the actual data measured with the H6180-01 Photon Counting Head, along with the corrected data obtained with the above equation. This proves that after making correction, the photon counting mode provides an excellent linearity with a count error of less than 1 %, even at a high count rate of 10^7 s^{-1}.
Figure 10 : Linearity of Count Rate

Figure 11 : Correction of Count Rate Linearity
3. Characteristics of Photomultiplier Tubes

3-1 Spectral Response (Quantum Efficiency)

When N number of photons enter the photocathode of a photomultiplier tube, the $N \times$ quantum efficiency (QE) of photoelectrons on average are emitted from the photo-cathode. The QE depends on the incident light wavelength and so exhibits spectral response.

Figures 12 (a) and (b) show typical spectral response characteristics for various photocathodes and window materials. The spectral response at wavelengths shorter than 350 nm is determined by the window material used, as shown in Figure 13.

In general, spectral response characteristics are expressed in terms of cathode radiant sensitivity or QE. The QE and radiant sensitivity have the following relation at a given wavelength.

$$QE = \frac{S \times 1240}{\lambda}$$

where S is the cathode radiant sensitivity in amperes per watt (A/W) at the given wavelength λ in nanometers.

Figure 12 : Typical Spectral Response Characteristics

Figure 12(a): Transmission Mode Photocathodes
Figure 12(b): Reflection Mode Photocathodes

Figure 13 : Typical Transmittance of Window Materials
3-2 Collection Efficiency

The collection efficiency (CE) is the probability in percent, that single photoelectrons emitted from the photocathode can be finally collected at the anode as the output pulses through the multiplication process in the dynodes. In particular, the CE is greatly affected by the probability that the photoelectrons from the photocathode can enter the first dynode. Generally, the CE is from 70 % to 90 % for head-on photomultiplier tubes and 50 % to 70 % for side-on photomultiplier tubes with full cathode illumination.

The CE is very important in photon counting measurement. The higher the value of the CE, the smaller the signal loss, thus resulting in more efficient and accurate measurements. The CE is determined by the photocathode shape, dynode structure and voltage distribution for each dynode.

As stated earlier, the ratio of the number of signal pulses obtained at the anode to the number of photons incident on the photocathode is referred to as the detection efficiency or counting efficiency.

Figure 14 shows the relation between the CE and the photocathode to first dynode voltage of 28 mm (1-1/8 ") diameter photomultiplier tubes, measured in the photon counting mode with the discrimination level kept constant and with small area illumination. As can be seen, the CE sharply varies at voltages lower than 100 V, but becomes saturated and shows little change when the voltage exceeds this. This means that a sufficient voltage should be applied across the photocathode and the first dynode to obtain stable CE.

Figure 14 : CE vs. Photocathode to First Dynode Voltage
3-3 Supply Voltage and Gain

The output pulse height of a photomultiplier tube varies with the supply voltage change, even when the light level is kept constant. This means that the gain of the photomultiplier tube is a function of the supply voltage. The secondary emission ratio δ is the function of voltage E between dynodes and is given by

$$\delta = A \cdot E^{\alpha}$$

where A is the constant and α is determined by the structure and material of the electrodes, which usually takes a value of 0.7 to 0.8.

Here, if we let n denote the number of dynodes and assume that the δ of each dynode is constant, then the change in the gain μ relative to the supply voltage V is expressed as follows:

$$\mu = \delta^{n} = (A \cdot E^{\alpha})^{n} = \left\{ A \cdot \left(\frac{V}{n+1} \right)^{\alpha} \right\}^{n}$$

$$= \frac{A^{n}}{(n+1)^{\alpha n}} \cdot V^{\alpha n} = K \cdot V^{\alpha n}$$

(K is a constant.)

Since typical photomultiplier tubes have 9 to 12 dynode stages, the output pulse height is proportional to the 6th to 10th power of the supply voltage. The curve previously shown in Figure 8 for the analog mode represents this characteristic.

Figure 15 : Gain vs. Supply Voltage
Figure 16 shows the relation between the secondary electorn emission ratio (δ_1) and the photocathode to first dynode voltage. The incident light is passed through a slit of 3 mm × 15 mm for side-on photomultiplier tubes, or is focused on a spot of 10 mm diameter for head-on photomultiplier tubes. It is clear that the secondary electron emission ratio depends on the material of the secondary electron emission surface. Generally, the larger the secondary electron emission ratio, the better the PHD will be.

Figure 16 : Secondary Electron Emission Yield vs. Supply Voltage
3-4 Noise

Various types of noise may exist in a photomultiplier tube even when it is kept in complete darkness. These noises adversely affect the counting accuracy, especially in cases where the count rate is low. The following precautions must be taken to minimize the noise effects.

(1) Thermionic Emission of Electrons

Materials used for photocathodes and dynodes have low work functions (energy required to release electrons into vacuum), so they emit thermal electrons even at room temperatures. Most of the noise is caused by these thermal electrons mainly being emitted from the photocathode and amplified by the dynodes. Therefore, cooling the photocathode is the most effective technique for reducing noise in applications where low noise is essential such as photon counting. In addition, since thermal electrons increase in proportion to photocathode size, it is important to select the photocathode size as needed.

Figure 17 shows temperature characteristics of dark counts measured with various types of photocathodes. These are typical examples and actual characteristics vary considerably with photocathode size and sensitivity (especially red sensitivity).

The head-on type Ag-O-Cs, multialkali, and GaAs photocathodes have high sensitivity in the near infrared, but these photocathodes tend to emit large amounts of thermal electrons even at room temperatures, so usually cooling is necessary.

Figure 17 : Temperature Characteristics of Dark Counts
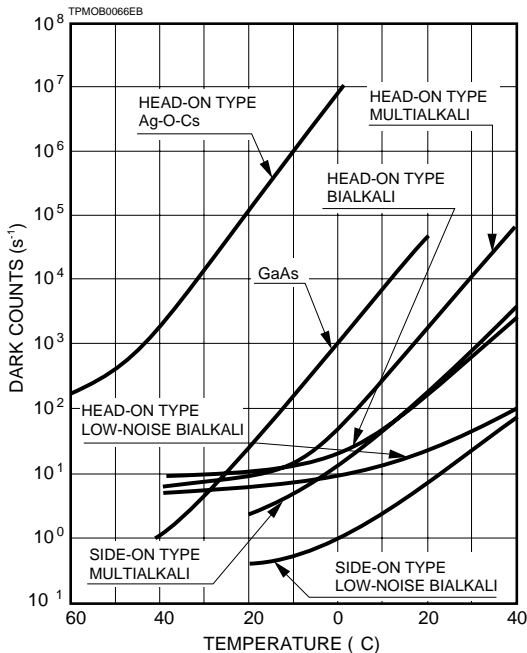

(2) Glass Scintillation

When electrons deviating from their normal trajectories strike the glass bulb of a photomultiplier tube, glass scintillation may occur and result in noise. Figure 18 shows typical dark current (RMS noise) versus the distance between the photomultiplier tube and the metal housing case at ground potential. This implies that glass scintillation noise is caused by stray electrons which are attracted to the glass bulb at a higher potential. This is particularly true when the tube is operated with a voltage divider circuit with the anode grounded. To minimize this problem, it is necessary to reduce the supply voltage for the photomultiplier tube, use a voltage divider circuit with the cathode grounded, or make longer the distance between the photomultiplier tube and the housing. Another effective measure is to coat the outer surface of the glass bulb with conductive paint which is maintained at the photocathode potential, in order to prevent stray electrons from being attracted to the glass bulb. In this case, however, the photomultiplier tube must be covered with an insulating material since a high voltage is applied to the glass bulb. We call this technique "HA coating". Although Figure 18 is an example of a side-on photomultiplier tube, similar characteristics will be observed for a head-on photomultiplier tube.

Figure 18 : Dark Current vs. Distance Between Photomultiplier Tube and Housing Case at Ground Potential
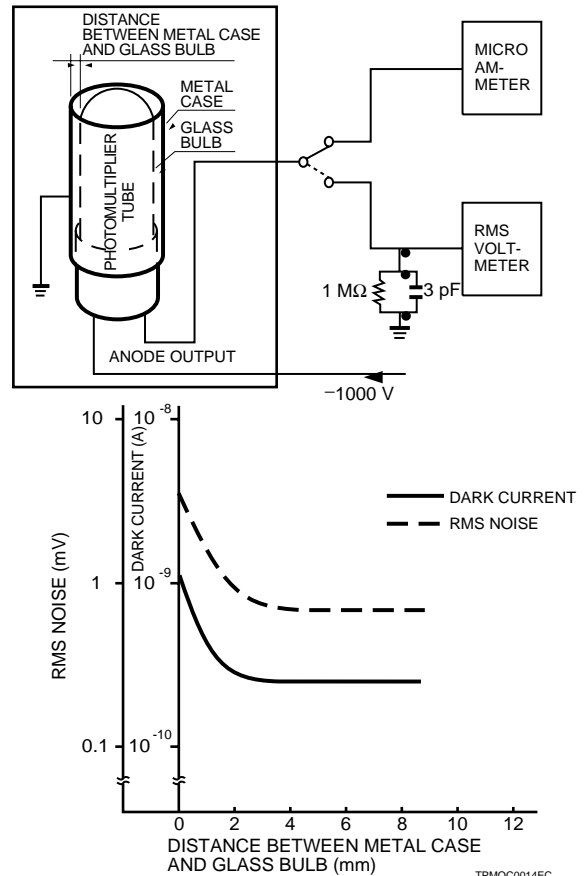

However, in most cases, the input window of the photomultiplier tube is exposed even with the HA coating. Therefore, in anode grounded scheme, use of good insulating material such as fluorocarbon polimers or polycarbonate is necessary around the input window in negative HV operation. Otherwise, a large potential difference may be created at the input window, and could result in irregular and high dark counts.

To avoid this problem, adopting a cathode grounded scheme is strongly recommended.

(3) Leakage Current

Leakage current may be another source of noise. It may increase due to imperfect insulation of photomultiplier tube base or socket pins, and also due to contamination on the circuit board. It is therefore necessary to clean these parts with appropriate solvent like ethyl alcohol.

In addition, when a photomultiplier tube is used with a cooler and if high humidity is present, the photomultiplier tube leads and socket are subject to frost or condensation. This also results in leakage current and therefore special attention should be paid.

(4) Field Emission Noise

This is voltage-dependent noise. When a photomultiplier tube is operated at a high voltage near the maximum rating, a strong local electric field may induce a small amount of discharge causing dark pulses. It is therefore recommended that the photomultiplier tube be operated at a voltage sufficiently lower than the maximum rating.

(5) External Noise

Besides the noise from the photomultiplier tube itself, there are external noises that affect photomultiplier tube operation such as inductive noise. Use of an electromagnetic shield case is advisable. Vibration may also result in noise mixing into the signal.

(6) Ringing

If impedance mismatching occurs in the signal output line from a photomultiplier tube, ringing may result, causing count error. This problem becomes greater in circuits handling higher speeds. The photomultiplier tube and the preamplifier should be connected in as short a distance as possible, or proper impedance matching should be provided at the input of the preamplifier.

3-5 Magnetic Shield

Most photomultiplier tubes are very sensitive to magnetic fields and the output varies significantly even with terrestrial magnetism (approx. 0.04 mT). Figure 19 shows typical examples of how photomultiplier tubes are affected by the presence of a magnetic field. Although photomultiplier

tubes in the photon counting mode are less sensitive to the magnetic field than in the analog mode, photomultiplier tubes should not be operated near any device producing a magnetic field (motor, metallic tools which are magnetized, etc.). When a photomultiplier tube has to be operated in a magnetic field, it is necessary to cover the photomultiplier tube with a magnetic shield case.

Figure 19 : Typical Effects by Magnetic Fields Perpendicular to Tube Axis
3-6 Stability and Dark Storage

In either the photon counting mode or analog mode, the dark current and dark count of a photomultiplier tube usually increase just after strong light is irradiated on the photocathode. To operate a photomultiplier tube with good

Figure 20 : Effect of Dark Storage in Noise Reduction
stability, it is necessary to leave the photomultiplier tube in dark state without allowing the incident light to enter the photocathode for about one or more hours. (This is called "dark storage" or "dark adaptation".) As Figure 20 shows, dark storage is effective in reducing the dark count rapidly in the actual measurement.

3-7 Uniformity

Uniformity is the variation in photomultiplier tube output with respect to the photocathode position at which light enters. As stated in 3-2 "Collection efficiency (CE)", even if uniform light enters the entire photocathode of a photomultiplier tube, some electrons emitted from a certain position of the photocathode are not efficiently collected by the first dynode (Dy1). This phenomenon causes variations in uniformity as shown in Figure 21. If photons enter a position of poor uniformity, not all the photoelectrons emitted from there are detected, thus lowering the detection efficiency. In general, head-on photomultiplier tubes provide better spatial uniformity than side-on photomultiplier tubes. For either type, good uniformity is obtained when light enters around the center of a photocathode.

Figure 21 : Typical Uniformity

(1) Head-on Type   (2) Side-on Type

TPMHC0085EB   TPMSC0030EB
3-8 Signal-to-Noise Ratio

This section describes theoretical analysis of the signal-to-noise consideration in both photon counting and analog modes. The noise being discussed here is mainly shot noise superimposed on the signal.

(1) Analog Mode

When signal light enters the photocathode of a photomultiplier tube, photoelectrons are emitted. This process occurs accompanied by statistical fluctuations. The photocathode signal current or average photocurrent I_{ph} therefore includes an AC component which is equal to the shot noise i_{ph} expressed below.

$$i_{ph} = \sqrt{2e I_{ph} B}$$

where e is the electron charge and B is the bandwidth of the measurement system.

The shot noise which is superimposed on the signal can be categorized by origin as follows :

a) Shot Noise Resulting from Signal Light
   Since the secondary electron emission in a photomultiplier tube occurs with statistical probability, the resulting output also has statistical fluctuation. Thus the noise current at anode, i_{sa}, is given by

$$i_{sa} = \sqrt{2e I_{ph} F B} \cdot \mu$$

where μ is the gain of the photomultiplier tube, F is the noise figure of the photomultiplier tube. If we let the secondary electron emission ratio per dynode stage be δn, the noise figure for the photomultiplier tube having n dynode stages can be expressed as follows:

$$F = \left(1 + \frac{1}{\delta_1} + \frac{1}{\delta_1 \cdot \delta_2} + \cdots\cdots + \frac{1}{\delta_1 \cdots\cdots \delta_n}\right)$$

Supposing that $\delta_1 = 5$, $\delta_2 = \delta_3 = \cdots\cdots = \delta_n = 3$, the noise figure takes a value of approximately 1.3 .
At this point, the photocurrent I_{ph} is given by

$$I_{ph} = \frac{P_i \, \eta(\lambda) \, \alpha e}{h \nu}$$

where P_i is the average light level entering the photomultiplier tube, $\eta(\lambda)$ is the photocathode QE at the wavelength λ, α is the photoelectron CE and $h\nu$ is the energy per photon.

b) Shot Noise Resulting from Background
    As with the shot noise caused by signal light, the shot noise at the anode resulting from the background P_b can be expressed as follows:

$$i_{ba} = \sqrt{2e I_b F B} \cdot \mu$$

$$I_b = \frac{P_b \eta(\lambda) \alpha e}{h \nu}$$

where I_b is the equivalent average cathode current produced by the background light.

c) Shot Noise Resulting from Dark Current
    Dark current may be categorized by cause as follows:
    ① Thermionic emission from the photocathode and dynodes.
    ② Fluctuation by leakage current between electrodes.
    ③ Field emission current and ionization current from residual gases inside the tube.
    Among these, a major cause of the dark current is thermionic emission from the photocathode.

13

Therefore the shot noise resulting from anode dark current i_{da} can be expressed as shown below:

$$i_{da} = \sqrt{2eI_d FB} \cdot \mu$$

where I_d is the equivalent average dark current from the photocathode.

d) Noise from Succeeding Amplifier
When an amplifier with noise figure F_a is connected to the photomultiplier tube load, the noise converted into the input of the amplifier is given by

$$I_{amp} = \sqrt{\frac{4F_a kTB}{R_{eq}}}$$

where R_{eq} is the equivalent resistance used to connect the photomultiplier tube with the amplifier, T is the absolute temperature and k is the Boltzmann constant.

e) Signal-to-Noise Ratio
Taking into account the background noise ($I_b + I_d$), the signal-to-noise ratio (S/N) of the photomultiplier tube output becomes

$$S/N = \frac{I_{ph}}{\sqrt{2eFB\{I_{ph}+2(I_b+I_d)\}+(4F_a kTB/R_{eq})/\mu^2}} \quad .. \ (1)$$

Among the above equations, the amplifier noise can be generally ignored because the gain μ of the photomultiplier tube is sufficiently large, so the signal-to-noise ratio can be expressed as follows:

$$S/N \approx \frac{I_{ph}}{\sqrt{2eFB\{I_{ph}+2(I_b+I_d)\}}} \quad .... \ (1)'$$

f) Noise Equivalent Power
In addition, the noise can also be expressed in terms of noise equivalent power (NEP). The NEP is the light level required to obtain a signal-to-noise ratio of 1, that is, the light level to produce a signal current equivalent to the noise current. The NEP indicates the lower limit of light detection and is usually expressed in watts.
From equation (1)' above, the NEP at a given wavelength can be calculated by using $I_b = 0$ and $S/N=1$, as follows:

$$S/N = \frac{I_{pha}}{\sqrt{2eF(I_{pha}+2I_{da})\mu B}} = \frac{S_p \cdot P_i}{\sqrt{2eF(S_p P_i+2I_{da})\mu B}}$$

where I_{pha} is anode signal current,
I_{da} is anode dark current,
and $I_{pha} = I_{ph} \cdot \mu = S_p \cdot P_i$
S_p: anode radiant sensitivity, P_i : input power
Then calculate the variable P_i.

$$S_p P_i = \sqrt{2eF(S_p P_i + 2I_{da})\mu B}$$

$$(S_p P_i)^2 - 2eF(S_p P_i+2I_{da})\mu B = 0$$

Therefore, NEP is given by P_i as follows:

$$P_i = \frac{eF\mu B}{S_p} + \frac{\sqrt{(eF\mu B)^2+4eFI_{da}\mu B}}{S_p}$$

In a low bandwidth region up to several kHz, the NEP mainly depends on the shot noise caused by dark current (the latter component in the above equation). In a high bandwidth region, the noise component (the former component in the above equation) resulting from the cathode radiant sensitivity (S_p/μ in the equation) predominates the NEP.
The noise can also be defined as equivalent noise input (ENI). The ENI is basically the same parameter as the NEP, and is expressed in lumens (S_p is measured in units of amperes per lumen in this case) or watts.

(2) Photon Counting Mode
In the analog mode, all pulse height fluctuations occurring during the multiplication process appear on the output. However, the photon counting mode can reduce such fluctuations by setting a discrimination level on the output pulse height, allowing a significant improvement in the signal-to-noise ratio.
In the photon counting mode in which randomly generated photons are detected, the number of signal pulses counted for a certain period of time exhibits a temporal fluctuation that can be expressed as a Poisson distribution. If we let the average number of signal pulses be N, it includes fluctuation (mean deviation) which is expressed in the shot noise $n = \sqrt{N}$. The amplifier noise can be ignored in the photon counting mode by setting the photomultiplier tube gain at a sufficiently high level, so that the discrimination level can be easily set higher than amplifier noise level.
As with the analog mode, dark current may be grouped by cause as follows:
(a) Shot noise resulting from signal light
$$n_{ph} = \sqrt{N_{ph}}$$
(N_{ph} is the number of counts by signal light)

(b) Shot noise resulting from background light
$$n_b = \sqrt{N_b}$$
(N_b is the number of counts by background light)

(c) Shot noise resulting from dark counts
$$n_d = \sqrt{N_d}$$
(N_d is the number of dark counts)

In actual measurement, it is not possible to detect N_{ph} separately. Therefore, the total number of counts ($N_{ph}+N_b+N_d$) is first obtained and then the background and dark counts (N_b+N_d) are measured over the same period of time by

14

removing the input light. Then N_{ph} is calculated by subtracting (N_b+N_d) from $(N_{ph}+N_b+N_d)$. From this, each noise component can be regarded as an independent factor, so the total noise component can be analyzed as follows:
Here, substituting $n_{ph}=\sqrt{N_{ph}}$, $n_b=\sqrt{N_b}$ and $n_d=\sqrt{N_d}$

$$n_{tot}=\sqrt{N_{ph}+2(N_b+N_d)}$$

Thus the signal-to-noise ratio (S/N) becomes

$$S/N=\frac{N_{ph}}{n_{tot}}=\frac{N_{ph}}{\sqrt{N_{ph}+2(N_b+N_d)}} \quad .... (3)$$

The number of counts per second for N'_{ph}, N'_b and N'_d is easily obtained as shown below, respectively. t is the measurement time in seconds.

$$N'_{ph}=N_{ph}/t, \ N'_b=N_b/t, \text{ and } N'_d=N_d/t$$

Accordingly, the equation (3) can be expressed as follows:

$$S/N=\frac{N'_{ph}\sqrt{t}}{\sqrt{N'_{ph}+2(N'_b+N'_d)}} \quad .... (3)'$$

This means that the signal-to-noise ratio can be improved as the measurement time is made longer.

By replacing the measurement time and the number of counts per second with the corresponding frequency and current, with $t=1/(2B)$ and $N'_x=I_x/e$ ($e=1.6\times10^{-19}$ C) respectively, it becomes clear that equation (1)' is equivalent to equation (3)' except for the noise figure term.

In photon counting mode, if we define the detection limit as the light level where the signal-to-noise ratio equals to 1, the number of signal count per second N'_{ph} at the detection limit can be approximated below, from equation (3)' under the condition that the measurement time is one second and the background light can be disregarded.

$$N'_{ph}\approx\sqrt{2N'_d} \ \ s^{-1} \quad .... (4)$$

At this point, if the dark count N'_d is more than several counts per second, the detection limit can be approximated with an error of less than around 30 %.

If we let the QE at a wavelength λ (nm) be $\eta(\lambda)$, the incident light power P_o at the detection limit can be approximated as follows:

$$P_o\approx\frac{2.8\times10^{-16}\times\sqrt{N'_d}}{\lambda\times\eta(\lambda)} \ \ W \quad ....(5)$$

For your reference, let us calculate the power (P) of a photon per second as follows:

$$P=\frac{hc}{\lambda}$$
$$\approx\frac{2\times10^{-16}}{\lambda} \ \ W$$

As an example, the table below shows the relation between the light power and the number of photons at a wavelength of 550 nm.

In contrast to the signal pulse height distribution (PHD) similar to a Poisson distribution, the dark current pulses are distributed on the lower pulse height side. This is because the dark current includes thermal electrons not only from the photocathode but also from dynodes. Therefore, some dark current component can be effectively eliminated by setting a proper discrimination level without reducing much of the signal component. Furthermore, by placing an upper discrimination level, the photon counting mode can also eliminate the influence of environmental radiation which produces higher noise pulses and often cause significant problems in the analog mode. It is now obvious that the photon counting mode allows the measurement with a higher signal-to-noise ratio than in the analog mode, which is even greater contribution than that obtained from the noise figure F.

4. Measurement Systems

Photon counting can be performed with several measurement systems, including simple sequential measurements and sampling measurements depending on the information to obtain or the light level and signal timing conditions.

4-1 Synchronous Photon Counting Using Chopper

Using a mechanical chopper to interrupt incident light, this method makes light measurements in synchronization with the chopper operation. More specifically, signal pulses and noise pulses are both counted during the time that light enters a photomultiplier tube, while noise pulses are counted during light interruption for subtracting them from signal pulses and noise pulses. This method is effective when a number of noise pulses are present or when extremely low level light is measured. However, since this method uses a mechanical chopper, it is not suitable for the measurement of high-speed phenomena. This method is also known as the digital lock-in mode. Figure 22 shows a block diagram for this measurement system, along with the timing chart.

Figure 22 : Synchronous Photon Counting Using Chopper

TPHOC0030EA
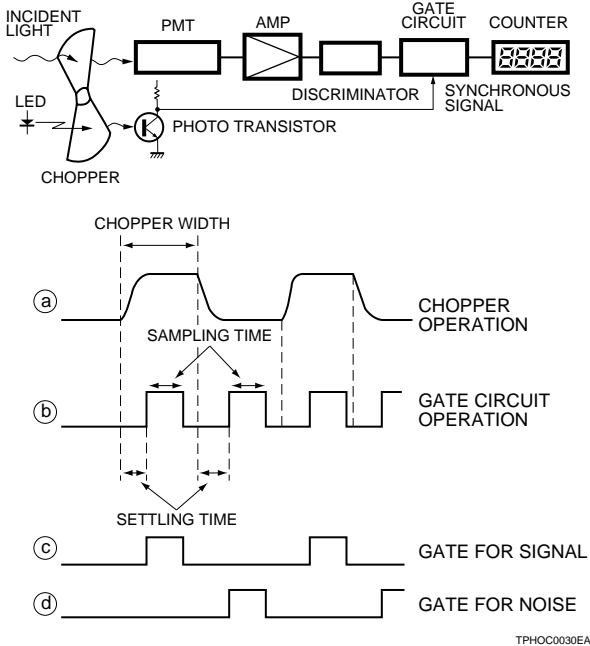

4-2 Time-Resolved Photon Counting by Repetitive Sampling

This method uses a pulsed light source to measure temporal changes of repetitive events.

Each event is measured by sampling at a gate timing slightly delayed from the repetitive trigger signals. The signal measured at each gate is accumulated to reproduce the signal waveform. This method is sometimes called the digital boxcar mode and is useful for the measurement of high-speed repetitive events. Figure 23 shows the time chart of this method.

Figure 23 : Time-Resolved Photon Counting by Repetitive Sampling

SITPHOC0031EB
4-3 Time-Resolved Photon Counting by Multiple Gates

This method sequentially opens multiple gates and measures the light level in a very short duration of the open gate, allowing a wide range of measurement from slow events to fast events. This method can also measure single events and random events by continuously storing data into memory. The time chart for this method is shown in Figure 24.

Figure 24 : Time-Resolved Photon Counting by Multiple Gates

TPHOC0032EB

16
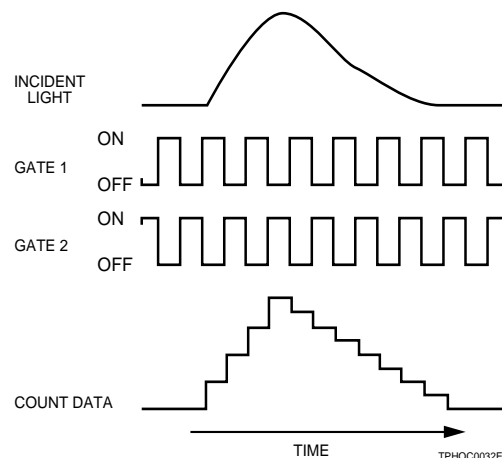

4-4 Time-Correlated Photon Counting

Time-correlated photon counting (TCPC) is used in conjunction with a high-speed photomultiplier tube for fluorescence lifetime measurement (in picoseconds to nanoseconds). By making the count rate sufficiently small relative to repetitive excitation light from a pulsed light source, this method measures time differences with respect to individual trigger pulses synchronized with excitation signals in the single photoelectron state.
Actual fluorescence and emission can be reproduced with good correlation by integrating the signals. Since this method only measures the time difference, it provides a better time resolution than the pulse width obtainable from a photomultiplier tube. A typical system for the TCPC consists of a high-speed preamplifier, a discriminator with less

time jitter called a constant fraction discriminator (CFD), a time-to-amplitude converter (TAC), a multichannel pulse height analyzer (MCA) and a memory or computer. Figure 25 shows the block diagram, time chart for this measurement system and one example data for fluorescence decay time.
Besides TCPC, time-resolved measurement also includes phase difference detection using the modulation method. This method is sometimes selected due to advantages such as a compact light source and simpler operating circuits.

5. Selection Guide

This section describes how to select the optimum photomultiplier tube for photon counting, along with their brief specifications and related products. The following notes should be taken into account in selecting the photomultiplier tube that matches your needs.

5-1 Selecting The Photomultiplier Tube

(1) Photomultiplier Tube Structure

Photomultiplier tubes are roughly grouped into side-on and head-on types, so it is important to select the photomultiplier tube structure type according to the optical measurement conditions.

Side-on photomultiplier tubes have a rectangular photosensitive area and are therefore suitable for use in spectrophotometers where the output light is in the form of a slit, or for the detection of condensed light or collimated light.

Head-on photomultiplier tubes offer a wide choice of photosensitive areas from 8 mm to 120 mm in diameter and can be used under various optical conditions. Note, however, that selecting the photomultiplier tube with a photosensitive area larger than necessary may increase dark counts, thus deteriorating the signal-to-noise ratio.

(2) Photocathode Quantum Efficiency (QE)

The QE has direct effects on the detection efficiency. It is important to select a photomultiplier tube that provides high QE in the desired wavelength range.

(3) Gain

Gain required of the photomultiplier tube differs depending on the gain or equivalent noise input of the amplifier connected. As a general guide, it is advisable to select a photomultiplier tube having a gain higher than 1×10^6, although it depends on the pulse width of the photomultiplier tube.

(4) Single Photoelectron Pulse Height Distribution (PHD)

Although not listed in the catalog, the PHD is an important factor since it relates to photomultiplier tube detection efficiency and stability. Hamamatsu designs photomultiplier tubes for photon counting, while taking the PHD into account. As a guide for estimating whether PHD is good or not, the peak to valley count ratio is sometimes used. (See Figure 6.)

(5) Dark Count → Lower Detection Limit

The dark count is an important factor for determining the lower detection limit of a photomultiplier tube. Selecting the photomultiplier tube with minimum dark counts is preferred. In general, for the same electrode structure, the dark count tends to increase with a larger photocathode and higher sensitivity in a long wavelength range. When a photomultiplier tube is used in a long wavelength range above 700 nm, cooling the photomultiplier tube is recommended.

(6) Response Time → Maximum Count Rate, Time Resolution

The maximum count rate (s^{-1}) in the photon counting mode is determined by the time response of the photomultiplier tube and the frequency characteristics of the signal processing circuit, or by the pulse width.

Most photomultiplier tubes have no problem with the time response up to a maximum count rate (random pulse) of 3×10^6 s^{-1}. However, in applications where the maximum count rate higher than this level is expected, a photomultiplier tube with the rise time (tr) shorter than 5 ns must be selected. In time-correlated photon counting (TCPC), the electron transit time spread (TTS) is more important than the rise time itself.

5-2 Photomultiplier Tubes for Photon Counting

Table 1 (on pages 28 and 29) is a listing of typical Hamamatsu photomultiplier tubes designed or selected for photon counting, showing general specifications for the spectral response and configurations. For more information, refer to the Hamamatsu photomultiplier tubes catalog. In addition to photomultiplier tubes listed in Table 1, you can choose from Hamamatsu photomultiplier tubes for photon counting. Please consult our sales office.

5-3 Related Products

There are many related products used in photon counting. The following sections introduce major products for photon counting available from Hamamatsu: preamplifiers, photon counting units, photon counting heads, photon counting boards, high-voltage power supplies, coolers and housings. For further details, refer to individual catalogs.

●Photon Counting Heads

<H7360-01, H6180-01, H6240 series>

These photon counting heads consist of a photomultiplier tube, a voltage divider, an amplifier, a discriminator and a high-voltage power supply, all included in a compact metallic case. The H7360-01, H6180-01 and H6240 series just require +5 V. All of these photon counting heads output TTL compatible signals for easy connection with pulse counters. Since the photomultiplier tube supply voltage and discrimination voltage are preset at the optimal levels, there is no need for adjustment before use. For the H7360-01 and H6180-01, the E6264 mount flange is optionally provided for connection to other equipment.

SPECIFICATIONS

Parameter	H7360-01	H6180-01	H6240	H6240-01	H6240-02	Unit
Sensitive Spectral Range	300 to 650	300 to 650	185 to 680	185 to 850	185 to 900	nm
Minimum Effective Area	ϕ 21	ϕ 15	4 x 20		4 x 6	mm
Counting Linearity Ⓐ (Random Pulse)	6×10^6	6×10^6	2.5×10^6			s^{-1}
Dark Count at +25 °C [Typ.]	15	10	30	80	400	s^{-1}
Output Pulse	Positive Logic : 3 V, 9 ns	Positive Logic : 3 V, 9 ns	Positive Logic TTL 30 ns			—
Input Voltage (Current)	+5 V (125 mA)	+5 V (125 mA)	+5 V (80 mA)			—

NOTE: Ⓐ At –10 % deviation from linear output.

<H7155 series>

H7155 series are compact photon counting heads comprising a metal package PMT, high-speed photon counting circuit, and high voltage power supply. The operation requires only connecting to a +5 V power supply and a pulse counter. There is no need for discrimination level or high voltage adjustment by users.

H7155 series accept direct light input or an optical fiber input. The fiber adaptor E5776 is optionally available.

The H7155-20 (300 nm to 650 nm) and -21 (300 nm to 850 nm) have a 1/4 prescaler to deliver a linear count rate of 1×10^7 s^{-1}.

SPECIFICATIONS

Parameter	H7155	H7155-01	Unit
Sensitive Spectral Range	300 to 650	300 to 850	nm
Minimum Effective Area	ϕ 8		mm
Counting Linearity (Random Pulse) Ⓐ	1.5×10^6		s^{-1}
Dark Count at +25 °C [Typ.]	100	600	s^{-1}
Output Pulse Width	Positive Logic TTL: 30 ns		—
Input Voltage (Current)	+5 V (50 mA Max.)		—
Dimensions (W x H x D)	22 x 50 x 50		mm

NOTE: Ⓐ At –10 % deviation from linear output.

<H7467 series>

The H7467 series is a compact photon counting head with the intelligence of a microcontroller. Since the detector interfaces diretly to a personal computer, the opeation only requires connecting to a +5 V power supply: no need for discrimination level or high voltage adjustment by users.

SPECIFICATIONS

Parameter	H7467	H7467-01	Unit
Sensitive Spectral Range	300 to 650	300 to 850	nm
Minimum Effective Area	ϕ 8		mm
Dark Count at +25 °C [Typ.]	1.5×10^6		s^{-1}
Counting Linearity Ⓐ	100	600	s^{-1}
Serial Interface Ⓑ	RS-232		—
Integration Time	10 to 10 000 (10 steps)		ms
Input Voltage (Current)	+5V (180 mA)		—

NOTES:Ⓐ At -10 % deviation rom linear output (random pulse.)
Ⓑ The Serial Interface requires the following communication specifications:9600 baud, No parity, 8 data bits, 1 stop bit.

<H3460 series>

The H3460 series photon counting heads incorporate a photomultiplier tube and a high-speed amplifier/discriminator into a compact metallic case. By connecting to an external high-voltage power supply for the photomultiplier tube and a low-voltage power supply for the amplifier/discriminator, photon counting can easily be performed.

Hamamatsu also offers the C3589 prescaler that divides the count rate by 10 for use with the H3460-53 and -54, allowing measurement over a wide dynamic range without using a high-speed counter.

SPECIFICATIONS

Parameter	H3460-53	H3460-54	Unit
Sensitive Spectral Range	300 to 650		nm
Minimum Effective Area	ϕ 21		mm
Counting Linearity (Random Pulse) Ⓐ	1.3×10^7		s^{-1}
Dark Count at +25 °C [Typ.]	20	40	s^{-1}
Output Pulse Width	ECL Balanced Line: 3 ns		—
Recommened High Voltage (Current) for Photomultiplier Tube	Approx. +1000 V (230 μA)		—
Input Voltages (Current) for Preamplifier and Discriminator	+5 V (35 mA), −5 V (150 mA)		—

NOTE: Ⓐ At −10 % deviation from linear output.

<H7421 series>

The H7421 series is a compact photon counting head consisting of a metal package PMT with a cooler, a high speed photon counting circuit and a high voltage power supply. The H7421-40 utilizes a GaAsP semiconductor photocathode which detects single photons from 300 nm to 720 nm in wavelength. The H7421-50 utilizes a GaAs semiconductor photocathode which detects single photons from 380 nm to 890 nm in wavelength. Both types have higher quantum efficiency compared to the conventional alkali metal photocathode at their peak wavelenghs.

By using a temperature monitor output from the thermistor, the operating temperature of the H7421 series can be monitored.

The output TTL signal can be handled easily by simply connecting to a counter.

To obtain good performance, the H7421 should be kept between +5 °C to +35 °C in operation.

SPECIFICATIONS

Parameter		H7421-40	H7421-50	Unit

● Photon Counting Unit
<C3866・C6465>

The C3866 photon counting unit converts photomultiplier tube output pulses into a 5 V digital signal by using a built-in amplifier/discriminator. Photon counting with high signal to noise ratio can be easily performed by connecting an external pulse counter to the output of the C3866 and supplying a low voltage. The high-speed electronic circuit used in the C3866 ensures high-precision photometry with high linearity up to 10^7 s^{-1}. Due to the built-in prescaler (division by 10), the C3866 does not require a high-speed pulse counter.

The C6465 offers high output linearity up to 10^6 s^{-1} and an output pulse width of 30 ns, allowing use with a general-purpose pulse counter.

SPECIFICATIONS

Parameter	C3866	C6465
Input Impedance	50 Ω	50 Ω
Discrimination Level (input equivalent)	−0.5 mV to −16 mV	−2.2 mV to −31 mV
Prescaler	÷1, ÷10	−
Maximum Count Rate (Random Pulse: −10 % deviation)	(÷1) 4×10^6 s^{-1}, (÷10) 1×10^7 s^{-1}	1×10^6 s^{-1}
Pulse Pair Resolution	(÷1) 25 ns, (÷10) 10 ns	60 ns
Output Pulse	CMOS 5 V	Positive TTL
Output Pulse Width	(÷1) 10 ns, (÷10) Depends on Count Rate	30 ns
Input Voltage (Current)	+5.2 V (150 mA), −5.2 V (300 mA)	+5 V (60 mA), −5 V (120 mA)
Dimensions (W × H × D)	88 mm× 32 mm× 170 mm	60 mm × 43.2 mm × 105 mm

● Photon Counting Board
<M7824>

The photon counting board M7824 is designed for direct plug-in to the ISA bus slot in a PC(Windows™ Me/98SE/98/95).Photoelectoron pulses converted into logic (TTL) signals are counted by M7824 and sent to a PC. A gate function is also included to make photon counting easier over a wide dynamic range.

M7824 applies a dual count method that allows time-resolved photon counting of high-speed optical phenomena with no dead time between gates. Simultaneous 2-channel measurements are also possible by using two M7824 boards.

SPECIFICATIONS

Parameter		Value
Input	Signal Input Level	TTL positive logic
	Signal Pulse Width	10 ns or more
	Input Impedance	50 Ω
Counter	Maximum Count Frequency	50 MHz
	Maximum Count per Gate	2^{32} counts
Gate	Internal Gate Time	50 μs to 10 s
	External Gate Time	100 ns or more
Trigger	Trigger Method	Software, external trigger input
	External Trigger	TTL negative logic
General-Purpose	Input Signal	TTL negative logic/ 8 bits
Output	Output Signal	Open collector/ 8 bits
OS		Windows™ Me/98SE/98/95
Bus Ⓐ		ISA bus
Address Space		Selectable with DIP switch on board
Input Voltage (Current) Ⓑ		5 V (1A)

NOTES:Ⓐ Contact Hamamatsu for using other interfaces.

　　　　Ⓑ This input voltage(current) is supplied through the ISA bus.

● Photon Counting Board

<M8503>

The photon counting board M8503 is designed for direct plug-in to the ISA bus slot in a PC (Windows™ Me/98SE/98/95). Photoelectron pulses converted into logic (TTL) signals are counted by the M8503 and sent to a PC. A gate function is included to make photon counting easier over a wide dynamic range.

The M8503 uses a dual count method that allows time-resolved photon counting of high-fast optical phenomena with no dead time between gates.

The gate time can be set as short as 50, 100 or 200 ns making the M8503 ideal for time-resolved photon counting of ultra-fast optical phenomena. An 8000 gate memory allows continuous measurements for up to 1.6 ms. The M8503 also has a built-in integration circuit for enhancing signal quality.

The M8503 delivers flexible, cost-effective high performance photon counting over a wide dynamic range.

● High Voltage Power Supplies

<C4900 series (on-board type)>

Aiming at compactness, low cost yet high performance, the C4900 series is a modular high-voltage power supply that can be directly mounted on a PC board. The newly designed circuitry ensures both high performance and low power consumption. Enhanced protective functions are also included as standard features.

SPECIFICATIONS

<C4710 series (on-board type)>

The C4710 series is an on-board type high-voltage power supply designed for photomultiplier tube operation.
It combines high performance with ease of use.

SPECIFICATIONS

Parameter		C4710	C4710-01	C4710-02	C4710-50	C4710-51	C4710-52	Unit
Input Voltage		+15±1	+12±1	+24±1	+15±1	+12±1	+24±1	V
Input Current [Typ.]Ⓐ	with no load	95	120	65	95	120	65	mA
	with full load	260	340	145	260	340	145	mA
Output Voltage Range		−240 to −1500			+240 to +1500			V
Maximum Output Current		1						mA
Line Regulation [Typ.] Ⓑ Against ±1 V Input Change		±0.01	±0.015	±0.015	±0.02	±0.02	±0.015	%
Load Regulation [Typ.] Ⓐ Against 0 % to 100 % Load Change		±0.01	±0.015	±0.01	±0.01	±0.01	±0.01	%
Ripple・Noise (p-p) [Typ.] Ⓑ		0.005						%
Dimensions (W × H × D)		65 × 27.5 × 45						mm

NOTES : Ⓐ At maximum output voltage.
Ⓑ At maximum output voltage and current.

<C3830, C4720 (bench-top type)>

The C3830 and C4720 are multipurpose power supplies that provide a high voltage output for photomultiplier tube operation
and low voltage outputs (±5 V, ±15 V) for peripheral devices such as the Hamamatsu preamplifier and photon counting unit.

SPECIFICATIONS

Parameter		High Voltage Power Supply Section		±5V Power Supply Section	±15V Power Supply Section	Unit
		C3830	C4720			
Output Voltages		−200 to −1500 (Variable)	+200 to +1500 (Variable)	±5(±0.25) (Fixed)	±15(±0.75) (Fixed)	V
Maximum Output Current Ⓐ		1		500	200	mA
Line Regulation [Typ.] Against ±10 % Line Voltage ChangeⒷ		±0.005		±0.005	±0.015	%
Load Regulation [Typ.] Against 0 % to 100 % Load Change Ⓐ		±0.01		±0.5	±0.5	%

AC Input Voltage	C3830	100/120/230 V (50 Hz/60 Hz)				—
	C4720	100/115/220 V (50 Hz/60 Hz)				

NOTES : Ⓐ At maximum output voltage.
Ⓑ At maximum output voltage and current.

\<C3350 (bench-top type)\>

The C3350 is a bench-top high-voltage power supply designed for general-purpose photomultiplier tube applications.

SPECIFICATIONS

Parameter	Value
Output Voltage	0 V to ±3000 V
Maximum Output Current Ⓐ	10 mA
Line Regulation [Max.] Against ±10 % Line Voltage Change Ⓑ	± (0.005 %+10 mV)
Load Regulation [Max.] Against 0 % to 100 % Load Change Ⓐ	±(0.01 %+50 mV)
Ripple•Noise (p-p) [Max.] Ⓑ	0.0007 %
AC Input Voltage	100/115/220/230 V (50 Hz/60 Hz)

NOTES : Ⓐ At maximum output voltage.
Ⓑ At maximum output voltage and current.

\<C3360 (bench-top type)\>

The C3360 is a bench-top high-voltage power supply specifically designed for the MCP-PMT operation.

SPECIFICATIONS

Parameter	Value
Output Voltage	0 V to –5000 V
Maximum Output Current Ⓐ	1 mA
Line Regulation [Max.] Against ±10 % Line Voltage Ⓑ	± (0.001 %+0.05 V)
Load Regulation [Max.] Against 0 to 100 % Load Change Ⓐ	± (0.001 %+0.05 V)
Ripple•Noise (p-p) [Max.]Ⓑ	0.0004 %
AC Input Voltage	85 V to 132 V / 170 V to 264 V

NOTES : Ⓐ At maximum output voltage.
Ⓑ ,At maximum output voltage and current.

● Coolers
\<C4877 series, C4878 series\>

In addition to high cooling capability, the C4877 series and C4878 series thermoelectric coolers are constructed with enhanced electrostatic and magnetic shielding. This minimizes the influence of external noise on the photomultiplier tube and thus significantly improves photometric accuracy. These coolers offer user-friendly functions such as easy temperature control and pilot lamp blanking.

The C4877 series is designed for use with 38 mm (1-1/2") or 51 mm (2 ") diameter head-on photomultiplier tubes and can be used with the E2762 series socket assembly or the C2759 series socket assembly with a built-in preamplifier ideal for photon counting. The C4878 series coolers are specifically designed for MCP-PMTs. (The E3059-500 holder is available.)

SPECIFICATIONS

Parameter	Description / Value
Cooling	Thermoelectric Effect
Heat Exchange Medium	Water
Water Flow Rate	1 L/min to 3 L/min
Temperature Controllable Range (with cooling water at +20 °C)	–30 °C to 0 °C
AC Input Voltage	100/120/230 V (50 /60 Hz)

\<C659 series\>

The C659 series is a water-cooled thermoelectric cooler that reduces photomultiplier tube temperature to –20 °C (C659-50) or –15 °C (C659-70). The C659-50 is designed for 28 mm (1-1/8 ") and 38 mm (1-1/2 ") diameter head-on photomultiplier tubes. The C659-70 is specifically intended for use with 28 mm (1-1/8 ") diameter side-on photomultiplier tubes. The E1135 series D-type socket assemblies are also provided for exclusive use with the C659 series coolers.

SPECIFICATIONS

Parameter	C659-50 series	C659-70 series
Cooling	Thermoelectric Effect	
Heat Exchange Medium	Water	
Water Flow Rate	1 L/min to 3 L/min	
Cooling TemperatureⒶ	Approx. –20 °C	Approx. –15 °C
AC Input Voltage	115/220V (50/60Hz)	

Ⓐ Cooling water : +20 °C, Cooling temperature may differ depending on the photomultiplier tube type.

● Housing
\<E1341 series\>

The E1341-01 is a metal housing designed for 51 mm(2") diameter head-on photomultiplier tubes operated at room temperature. The E5859 series D-type socket assembly is also available, which can be housed in the E1341-01 along with a PMT. The E1341-01 ensures complete light-shielding and also accommodates a magnetic shield case(E989-62 sold separately).

The E1341-01 housing can be easily attached to a monochromator by preparing a simple adapter.The Copal No.3 shutter can be directly attached to the E1341-01.

● High-Speed Amplifier
\<C5594 series\>

The C5594 series is a wide-band amplifier with a high gain. The frequency cut-off is as high as 1.5 GHz, enabling amplification of high-speed output pulses from all types of photomultiplier tubes with good fidelity. In particular, the C5594 series is ideally suited for fluorescence lifetime measurement in single photon level using an MCP-PMT and other timing property measurements using high-speed photomultiplier tubes. The input/output connectors are available in either BNC or SMA configuration. For more details, refer to the individual data sheet.

SPECIFICATIONS

Parameter	Value
Input Voltage	+12 V to +16 V
Maximum Input Signal Power	10 mW
Frequency Bandwidth (–3 dB)	50 kHz to 1.5 GHz
Gain	36 dB (63 Times)
Input / Output Impedance	50 Ω
Current Consumption	95 mA

● D-type Socket Assemblies

Hamamatsu provides D-type socket assemblies using a voltage divider circuit tailored for photon counting.
A variety of types are available for use with different size photomultiplier tubes.

13mm (1/2 ") diameter side-on tubes E850-22
28mm (1-1/8 ") diameter side-on tubes .... E717-500, -501
10mm (3/8 ") diameter head-on tubes .... E1761-21, -22
13mm (1/2 ") diameter head-on tubes .... E849-52, -90
19mm (3/4 ") diameter head-on tubes .... E974-17, -18, -22
25mm (1 ") diameter head-on tubes E2924-500
28mm (1-1/8 ") diameter head-on tubes E990-500, E2624-500
52mm (2 ") diameter head-on tubes .... E2979-501, E5859-01, -05

Besides those listed above, D-type socket assemblies specifically designed for use with coolers are provided.
Please contact our sales office.

For C659 series coolers .... E1135-500, -501, -502, -503, -504
For C4877 series coolers .... E2762-502, -504, -506, -509,- 510

We also have the C6270, which has built-in high voltage power supply with divider, for 28 mm (1-1/8 ") diameter
side-on photomultiplier tubes.

⚠ WARNING

HIGH VOLTAGE

● High voltage power supplies and other products contained in this brochure generate or exhibit hazardous voltage and may present an electric shock hazard.

● The products contained in this brochure should be installed, operated, or serviced only by qualified personnel that have been instructed in handling high voltages.

● The products contained in this brochure should be installed, operated, or serviced in accordance with what are instructed in their instruction manuals and other relevant Hamamatsu publications.

● Designs of equipment utilizing the products contained in this brochure should incorporate appropriate interlocks to protect the operator and service personnel from electric shocks.

Subject to local technical requirements and regulations, availability of products included in this promotional material may vary.
Please consult with our sales office.
